Python

- **Description:**

Python is a high-level, interpreted programming language known for its easy-to-read syntax. It's very popular in data science due to its versatility and the wide array of libraries available for data analysis, visualization, and machine learning.

- **Usage:**

In data science, Python is used for data cleaning, analysis, visualization, statistical modeling, and machine learning.

- **How to Install:**

You can install Python by downloading the appropriate installer for your operating system from the [Python official website](#).

Version: 3.9

- **How to Check if It's Already Installed:**

```
python --version
```

```
# or sometimes it might be python3
python3 --version
```

Anaconda

- **Description:**

Anaconda is a distribution of Python and R for scientific computing and data science. It simplifies package management and deployment and comes with a bundle of pre-installed data science packages.

- **Usage:**

Anaconda is used to create environments for projects with specific package versions, including but not limited to Jupyter notebooks, NumPy, pandas, and scikit-learn.

- **How to Install:**

Download the Anaconda installer from the [Anaconda website](#) and follow the instructions for your operating system.

MacOs: https://www.youtube.com/watch?v=oWVTO_69U4c

Windows: <https://www.youtube.com/watch?v=YU7ZGgPKSsA&t=3s>

- **How to Check if It's Already Installed:**

```
conda --version
```

Git

- **Description:**

Git is a distributed version control system that helps you track changes in your code over time. It also allows multiple people to work on the same codebase

simultaneously.

- **Usage:**

In data science, Git is used for version control of code, collaboration with other data scientists, and for tracking changes to data analysis scripts and notebooks.

- **How to Install:**

For most systems, Git can be installed from the command line:

- On macOS: `brew install git` (using Homebrew)
- On Ubuntu/Debian: `sudo apt-get install git`
- On Windows: Download and install from [Git's website](#).

- **How to Check if It's Already Installed:**

```
git --version
```

Set Up GitHub Account

- **Description:**

GitHub is a web-based platform for version control and collaboration. It uses Git for tracking changes in source code during software development.

- **Usage:**

GitHub is used to store repositories online, track issues, collaborate with others, and share your projects with the world.

- **How to Install:**

Setting up a GitHub account does not require an installation. Simply go to [GitHub's website](#) and sign up for an account.

- **How to Check if It's Already Installed:**

Since GitHub is not a software you install, you would check if you have an account by attempting to log in to the website.

- **Description:**

Jupyter Notebook is an open-source web application that allows you to create and share documents that contain live code, equations, visualizations, and narrative text.

- **Usage:**

Used for data cleaning and transformation, numerical simulation, statistical modeling, data visualization, and machine learning.

- **How to Install:**

If you have installed Anaconda, Jupyter Notebook is included.

Pip

- **Description:**

`pip` is the package installer for Python. You can use it to install packages from the Python Package Index (PyPI) and other indexes.

- **Usage:**

`pip` is used to install and manage software packages written in Python. It connects to an online repository of public and private packages, allowing users to download and install them.

- **How to Install:**

`pip` is already installed if you're using Python 2 >=2.7.9 or Python 3 >=3.4 downloaded from `python.org` or if you are working in a Virtual Environment created by `virtualenv` or `pyenv`. Otherwise, you can install `pip` by following the instructions provided in the [pip documentation](#).

- **How to Check if It's Already Installed:**

```
pip --version
# or for Python 3 specifically
pip3 --version
```

It's important to note that sometimes you may have multiple versions of Python installed on your system (e.g., Python 2.x and Python 3.x). Therefore, you might

need to use `pip2` or `pip3` to install packages for the specific Python version you are using.

Furthermore, when working with Anaconda, you might use `conda` to install packages that are available in the Anaconda repository and `pip` for packages that are only available in PyPI or for which you need the latest version not yet available in the Anaconda repository. In such cases, it is best practice to install as many requirements as possible with `conda` before using `pip`.
